Problem Set 3

Tianxin Zhang 21352232 Applied Stats II

Due: March 26, 2023

Instructions

- Please show your work! You may lose points by simply writing in the answer. If the problem requires you to execute commands in R, please include the code you used to get your answers. Please also include the .R file that contains your code. If you are not sure if work needs to be shown for a particular problem, please ask.
- Your homework should be submitted electronically on GitHub in .pdf form.
- This problem set is due before 23:59 on Sunday March 26, 2023. No late assignments will be accepted.

Question 1

We are interested in how governments' management of public resources impacts economic prosperity. Our data come from Alvarez, Cheibub, Limongi, and Przeworski (1996) and is labelled gdpChange.csv on GitHub. The dataset covers 135 countries observed between 1950 or the year of independence or the first year forwhich data on economic growth are available ("entry year"), and 1990 or the last year for which data on economic growth are available ("exit year"). The unit of analysis is a particular country during a particular year, for a total > 3,500 observations.

- Response variable:
 - GDPWdiff: Difference in GDP between year t and t-1. Possible categories include: "positive", "negative", or "no change"
- Explanatory variables:
 - REG: 1=Democracy; 0=Non-Democracy
 - OIL: 1=if the average ratio of fuel exports to total exports in 1984-86 exceeded 50%; 0= otherwise

Please answer the following questions:

1. Construct and interpret an unordered multinomial logit with GDPWdiff as the output and "no change" as the reference category, including the estimated cutoff points and coefficients.

Table 1: mult.log Results

	$Dependent\ variable:$	
	negative	positive
	(1)	(2)
REG	1.379*	1.769**
	(0.769)	(0.767)
OIL	4.784	4.576
	(6.885)	(6.885)
Constant	3.805***	4.534***
	(0.271)	(0.269)
Akaike Inf. Crit.	4,690.770	4,690.770
Note:	*p<0.1; **p<0.05; ***p<0	

Interpretation:

Negative vs. no change model:

Coefficient for REG: Holding other covariates constant, for every one unit change in regime type, from non-democracy to democracy, we expect to see an increase in the log-odds of GDP change negatively vs. no change in GDP by 1.379 on average.

Coefficient for OIL: Holding other covariates constant, for every one unit change in oil exportation, from "the average ratio of fuel exports to total exports in 1984-86 did not exceeded 50%" to "the average ratio of fuel exports to total exports in 1984-86 exceeded 50%", we expect to see an increase in the log-odds of GDP change negatively vs. no change in GDP by 4.784 on average.

Positive vs. no change model:

Coefficient for REG: Holding other covariates constant, for every one unit change in regime type, from non-democracy to democracy, we expect to see an increase in the log-odds of GDP change positively vs. no change in GDP by 1.769 on average.

Coefficient for OIL: Holding other covariates constant, for every one unit change in oil exportation, from "the average ratio of fuel exports to total exports in 1984-86 did not exceeded 50%" to "the average ratio of fuel exports to total exports in 1984-86 exceeded 50%", we expect to see an increase in the log-odds of GDP change positively vs. no change in GDP by 4.576 on average.

2. Construct and interpret an ordered multinomial logit with GDPWdiff as the outcome variable, including the estimated cutoff points and coefficients.

```
# run ordered multinomial regression
data$GDPWdiff_reo <- factor(data$GDPWdiff_reo , levels = c("negative", "no change", "positive"))
ord.log <- polr(GDPWdiff_reo ~ REG + OIL, data = data, Hess = TRUE)
summary(ord.log)
stargazer(ord.log, title="ord.log Results")</pre>
```

Interpretation:

Coefficient for Regime type: Holding other covariates constant, one unit change in the regime type, from the category of non-democracy to democracy, we expect to see an increase in the log odds of change in GDP in the positive direction by 0.398 on average.

Coefficient for OIL: Holding other covariates constant, for every one unit change in oil exportation, from "the average ratio of fuel exports to total exports in 1984-86 did not exceeded 50%" to "the average ratio of fuel exports to total exports in 1984-86 exceeded 50%", we expect to see an decrease in the log-odds of GDP change in a positive

Table 2: ord.log Results

	Dependent variable:
	${\rm GDPWdiff_reo}$
REG	0.398***
	(0.075)
OIL	-0.199^*
	(0.116)
Observations	3,721
Note:	*p<0.1; **p<0.05; ***p<0.01

direction by 0.199 on average.

Question 2

Consider the data set MexicoMuniData.csv, which includes municipal-level information from Mexico. The outcome of interest is the number of times the winning PAN presidential candidate in 2006 (PAN.visits.06) visited a district leading up to the 2009 federal elections, which is a count. Our main predictor of interest is whether the district was highly contested, or whether it was not (the PAN or their opponents have electoral security) in the previous federal elections during 2000 (competitive.district), which is binary (1=close/swing district, 0="safe seat"). We also include marginality.06 (a measure of poverty) and PAN.governor.06 (a dummy for whether the state has a PAN-affiliated governor) as additional control variables.

(a) Run a Poisson regression because the outcome is a count variable. Is there evidence that PAN presidential candidates visit swing districts more? Provide a test statistic and p-value.

Table 3: mod.ps Results

	$Dependent\ variable:$	
	PAN.visits.06	
competitive.district	-0.081	
-	(0.171)	
narginality.06	-2.080***	
	(0.117)	
PAN.governor.06	-0.312^*	
	(0.167)	
Constant	-3.810***	
	(0.222)	
Observations	2,407	
Log Likelihood	-645.606	
Akaike Inf. Crit.	1,299.213	
Note:	*p<0.1; **p<0.05; ***p<	

5

```
cfs \leftarrow coef(mod.ps)
cfs[2] # coefficient for competitive.dsitrict
se_cd <- result \ coefficients [2, 2]
14 se_cd # standard error of competitive. district
16 ## I will conduct a Z test to test individual coefficient for the
     variable Competitive. district
17 ## I set 95% as our confidence interval
18 ## H0: B1 = 0
19 ## Ha: B0 not equals to 0
20 ## Z test score:
z = (cfs[2] - 0)/se_cd
\mathbf{z} \ \# \ -0.4766106
24 # two-tail, p-value
p = 2*pnorm(-0.4766106, lower.tail=FALSE)
27 # p value: 1.366, which is larger than 5%. Therefore, we cannot rejct the
      null hypothesis that
28 # the coefficient for the competitive district equals to 0.
```

Therefore, there is no sufficient evidence that PAN presidential candidate will visit swing districts more.

- (b) Interpret the marginality.06 and PAN.governor.06 coefficients.
 - 1. Interpretation of the coefficient for marginality.06: Holding all other covariates constant, for a one unit change in marginality.06, from the category of not-marginal to the category of marginal, the logs of expected counts of visit is expected to decrease by 2.080.
 - 2. Interpretation of the coefficient for PAN.governor.06: Holding all other covariates constant, for a one unit change in PAN.governor.06, from the category of not PAN.governor to the category of PAN.governor, the logs of expected counts of visit is expected to decrease by 0.312.
- (c) Provide the estimated mean number of visits from the winning PAN presidential candidate for a hypothetical district that was competitive (competitive.district=1), had an average poverty level (marginality.06 = 0), and a PAN governor (PAN.governor.06=1).

```
7 predict(mod.ps, newdata= pred, type = "response")
9 # 0.01494818
10
11
12
13 exp(cfs[1] + cfs[2] * 1 + cfs[3] * 0 + cfs[4] *1)
14
15 ## 0.01494818
16
17 ## In conclusion, the estimated mean number of visit is 0.
```
